From ancient times, Georgia was rich in vine varieties. It is of great importance to study old and modern vine varieties, since this proves that Georgia is a country of traditional viticulture. Of course, many vine varieties were made with wine. In turn, we can identify winemaking areas by studying vine varieties. There is a great deal of information on the production of vines and wine in ancient sources, and it is in this abundance that it is important to create a unified database using modern information technology GIS systems.

Due to the diverse range of native and culturally native Aboriginal vine varieties in our country, the toponyms associated with them are abundant. Particularly noteworthy for me were the geographical names where the names of the now forgotten vine varieties are retained. It turns out that these names reflect the spread of vines in the past, and on the other hand indicate the spread of vines in a once specific area and subsequently the destruction of vines there. It also encountered many vine varieties, the name of which comes from the area where it was distributed.

There were varieties named after their ampelographic characters. After processing various literary sources, a database was created containing various information on the varieties of vines. This database is compiled using geoinformatics systems. Send feedback History Saved Community.
